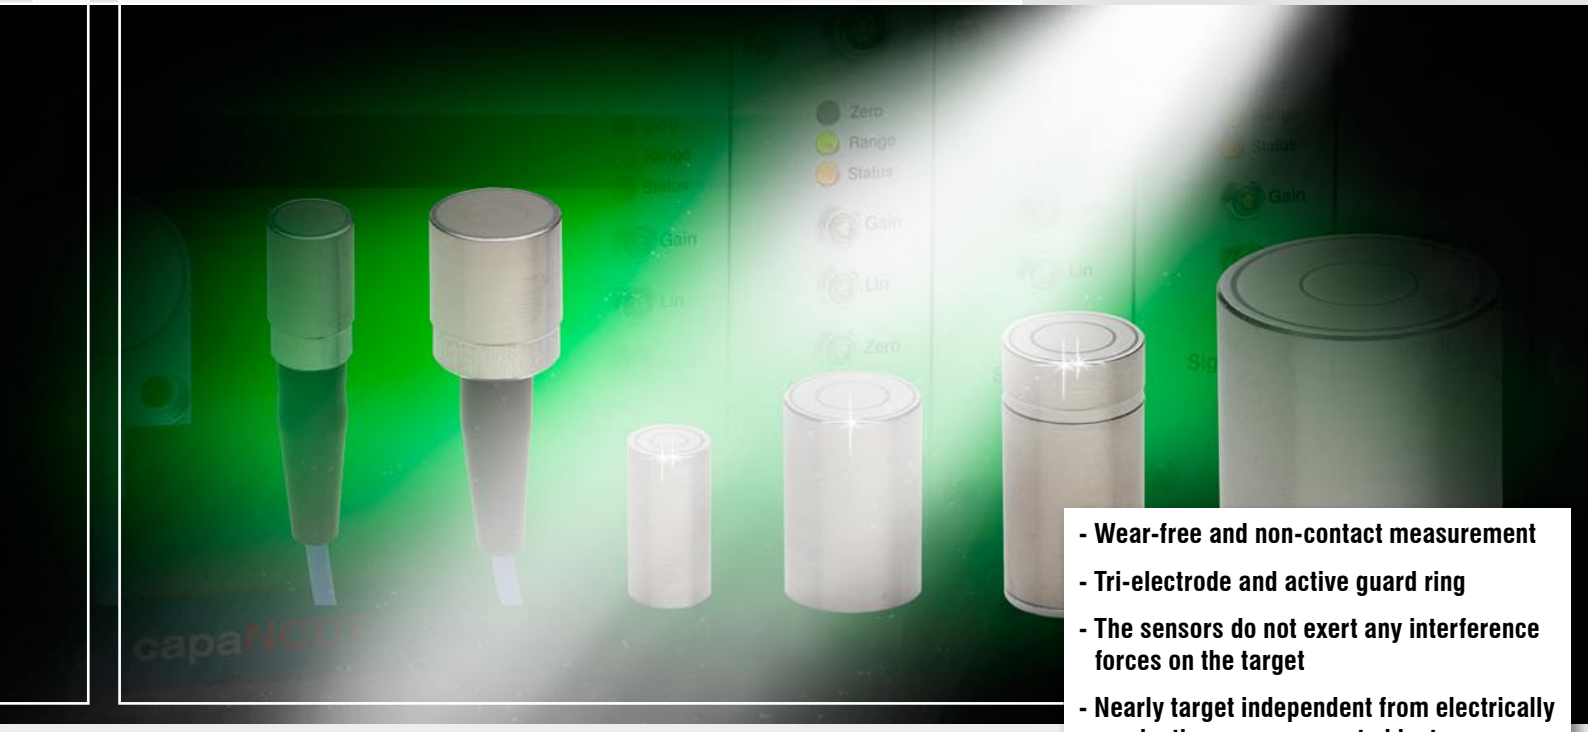
MICRO-EPSILON

More Precision.

capaNCDT

High resolution capacitive displacement sensors and systems.

Measuring principle



- **Wear-free and non-contact measurement**
- **Tri-electrode and active guard ring**
- **The sensors do not exert any interference forces on the target**
- **Nearly target independent from electrically conductive measurement objects**

Measuring principle

The principle of capacitive displacement measurement using the capaNCDT (capacitive Non-Contact Displacement Transducer) system is based on how an ideal plate-type capacitor operates. The two plate electrodes are represented by the sensor and opposing measurement object. If a constant alternating current flows through the sensor capacitor, the amplitude of the alternating voltage on the sensor is proportional to the distance between the capacitor electrodes. The alternating current is demodulated and output as, for example, an analogue signal.

The capaNCDT system evaluates the reactance of the plate capacitor, which changes in direct proportion to the distance.

$$X_C = \frac{1}{j \cdot \omega \cdot C}$$

$$\text{Capacitance } C = \varepsilon_r \cdot \varepsilon_0 \cdot \frac{\text{area A}}{\text{distance d}}$$

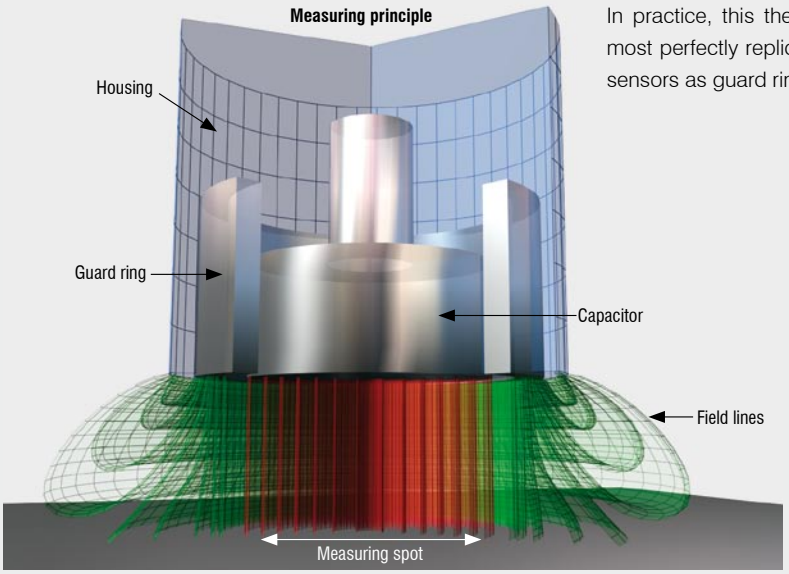
Due to the fact that $j\,\omega\,\varepsilon_r\varepsilon_0$ and A do not change during measurements, they are sustituted with a constant:

$$\text{constant } K = \frac{1}{j\omega\varepsilon_r\varepsilon_0 A}$$

According to that, the reactance X_C only depends from the distance:

$$X_C = \text{constant} \cdot \text{distance}$$

In practice, this theoretical relationship is almost perfectly replicated by the design of the sensors as guard ring capacitors.



Use of capacitive sensors

Capacitive sensors are always used if very high accuracy levels are required. The capacitive measuring principle is one of the most precise measurement methods for non-contact displacement measurement.

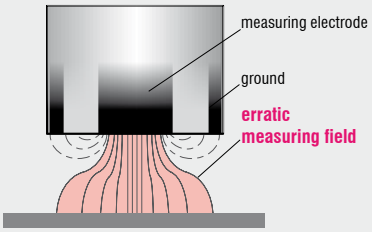
The measurement principle requires a clean environment where a change of the dielectric ε_r affects the measurement result. The sensors measure against all electrically conductive materials.

Use in a vacuum and clean room

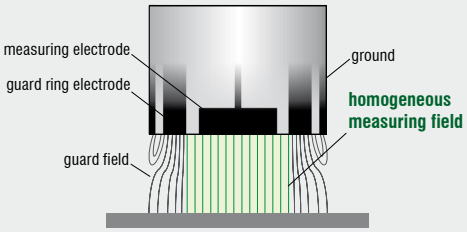
Sensors and sensor cables have proven themselves in clean rooms and under a vacuum. The extremely low gas release is responsible for this. capaNCDT Sensors for ultrahigh vacuum area (UHV) are available on request.

Active guard field for high precision measurement

Common capacitive sensors



MICRO-EPSILON capaNCDT sensors



Triaxial sensor design

The completely triaxial sensor design is unique for capaNCDT sensors, where the guard ring electrode and the grounding are also located on the front edge of the sensor as well as the measurement electrode.

This means capaNCDT sensors can also be installed completely flush in conductive materials. The sensors can also come into contact with each other in the case of multi-channel measurements. Interference of the measuring field is reliably prevented by the triaxial design of the sensor.

Active guard triaxial cable

Capacitive measurement systems from Micro-Epsilon operate with a unique, active, low noise cable in combination with an active guard ring capacitor. A particularly high quality signal is achieved due to the double shielding of the field. The system has an almost perfect impermeable electrical shield, which ensures precise measurements. In addition, the guard ring electrode provides a protected, completely homogeneous measuring field for extremely high stability and interference-free, accurate measurements.

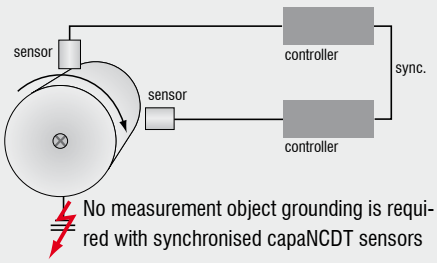
Rapid sensor replacement without calibration

The capacitive measuring principle specially developed by Micro-Epsilon enables the simple change of a sensor in just a few seconds. This simplified replacement of sensors with different measuring ranges and the interchange of different capaNCDT controllers can be easily carried out without any re-calibration. A sensor replacement normally takes around 5 seconds, unlike conventional systems, which have to be subjected to time-consuming calibration and linearisation.

Fast sensor replacement in just 5 seconds!
The interchange of various controllers and sensors in the capaNCDT series is performed rapidly without any time-consuming calibration.

Non-contact target grounding

In many applications, grounding of the target is very difficult or even impossible. Unlike conventional systems, the target for synchronisation of two capaNCDT devices does not necessarily have to be grounded. However, maximum signal quality is only achieved when the measurement object is correctly grounded. All measurement objects must be grounded for applications that use DT6019.

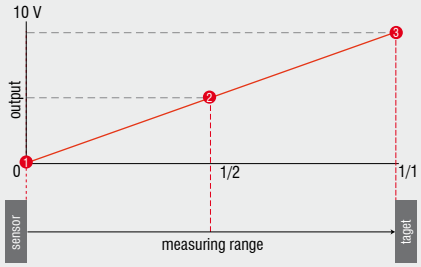


No measurement object grounding is required with synchronised capaNCDT sensors

The schematic diagram shows two synchronised capaNCDT sensors that are measuring against a roller. As the sensors are connected via Micro-Epsilon's unique synchronisation technology, grounding of the target is unnecessary in most cases.

Linearisation and calibration

capaNCDT systems are calibrated at the factory for metallic targets (output 0 – 10V). The nominal output characteristic can be optimised by the user for special target materials or difficult installation conditions using the "Zero Point" potentiometer. Three-point linearisation is necessary for insulators as target. The adjustment is made using three distance points (1 = zero point, 2 = measuring range centre, 3 = measuring range end), which are defined as comparison standard.



This calibration can be performed for the capaNCDT 6300 and 6500 models.

Sensors

The sensors are designed as guard ring capacitors. They are connected to the signal conditioning electronics with a triaxial cable. The sensor cable is connected to the sensor using a high quality connector. All standard sensors can be used within a maximum deviation of 0.3% without recalibration. Individually matched special sensors are produced on request.

Measuring range expansion / reduction

The capaNCDT controller (except the series DT6019) can optionally be configured so that the standard measuring ranges of the sensors are reduced by half or expanded by the factor of 2. The reduction increases the accuracy while the measuring range expansion reduces the accuracy.

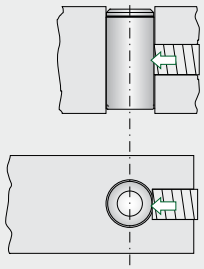
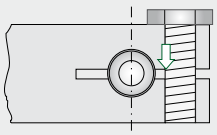
Mounting cylindrical sensors

All sensors can be installed as both freestanding and flush units.
Fastening is carried out by using a clamp or collet.

Mounting with grub screw (plastic)



Mounting with collet



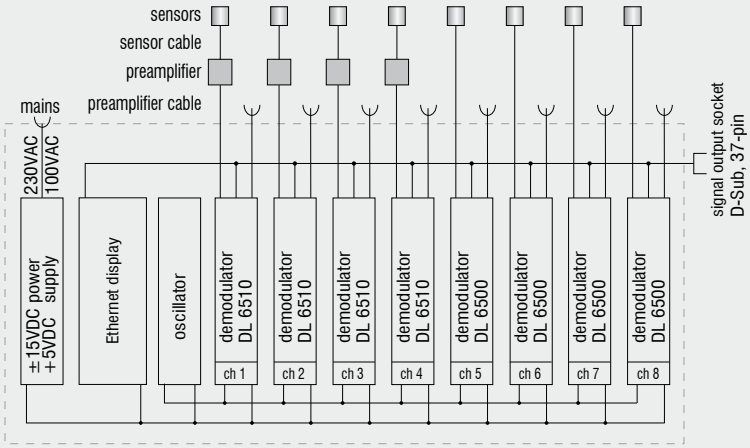
Important!
All Micro-Epsilon sensors are short circuit proof. Unlike other systems the pre-amplifier will not get damaged, if the front face of the sensor gets shorted by touching the conductive target

- **Multi-channel system**
- **Sub-nanometre precision resolution**
- **Virtually independent of temperature**
- **Material-independent for conductive materials**
- **As benchtop unit and as card carrier for a 19-inch format**
- **Also measures against insulators**
- **Integrated calculation function for thickness measurements**
- **Numerous filters, averaging, trigger functions, measured value storage, digital linearisation**
- **Suitable for all sensors**

System structure

The capaNCDT 6500 can be used for multi-channel operation and is modular in its design. Up to eight sensors can be connected to the signal conditioning electronics (Euro-size cards) via a pre-amplifier module.

For the DL6500 version, the pre-amplifier is integrated in the housing and is used for cable lengths up to 4m. For cable lengths above 4m, the DL6510 version is used together with an external pre-amplifier CP6001 or CPM6011.



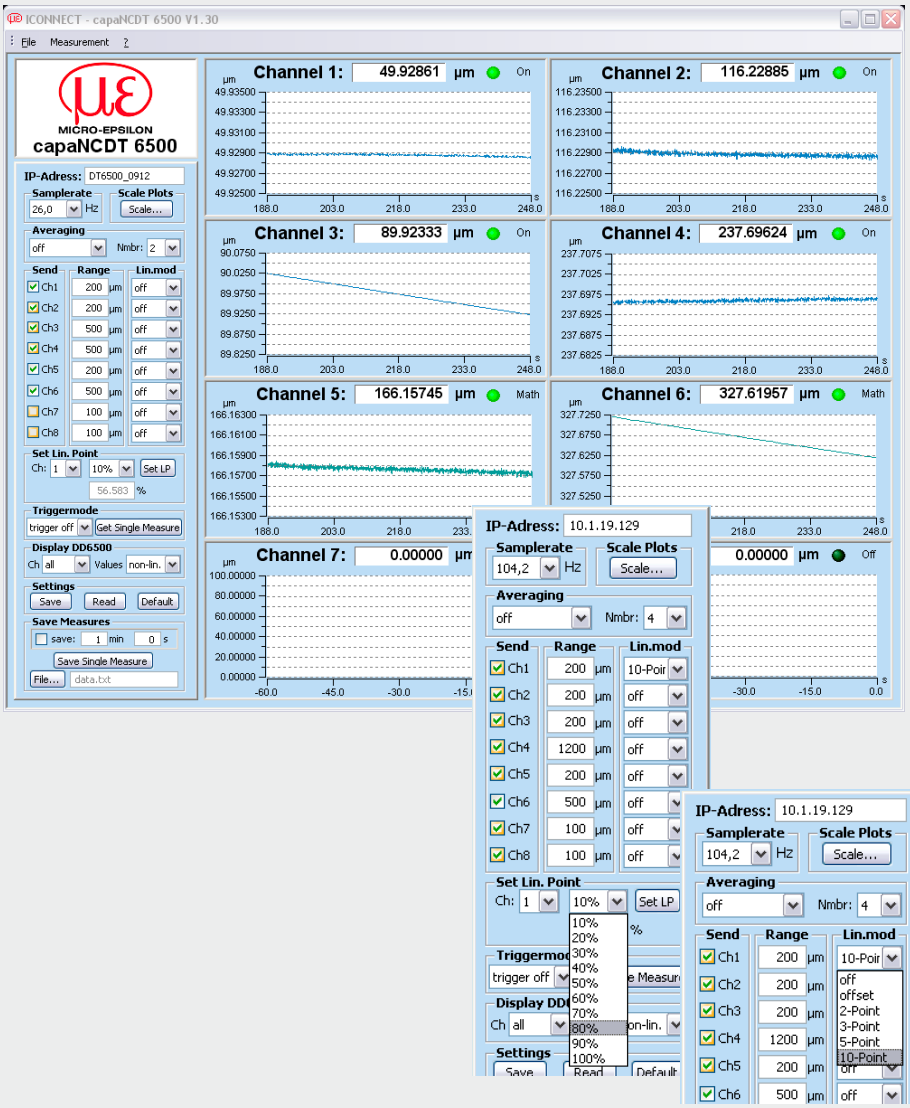
A measuring system with n measurement channels consists of:

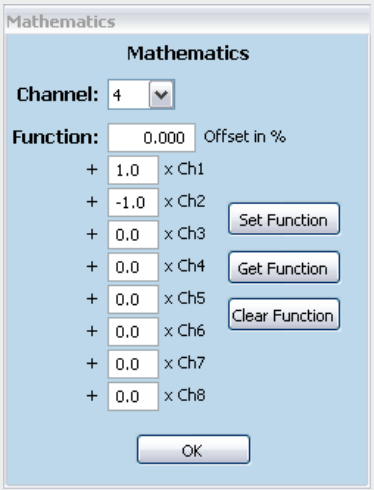
1. controller RS6500 with power supply, display, ethernet, oscillator and analog output
2. n x demodulator modules DL6510 (DL6500 with integral pre-amplifier)
3. n x pre-amplifier connecting cables
4. n x pre-amplifier modules CP6001
5. n x sensor cables
6. n x sensors

DL6510: One item of position 2 to 6 is needed for each channel.
DL6500: One item of position 2, 5 and 6 is needed for each channel.
In the case of a distance from the sensor to the controller > 4m,
a DL6510 demodulator with external pre-amplifier must be used.

Software

Digital values can be visualised and processed using the software supplied.





Calculation Functions
The digital values can be arithmetically linked in numerous ways.

10-point Linearisation
Linearisation of the digital values with up to 10 points. The linearisation only acts on the digital signals and is performed directly in the DT6500.

System configuration

System capaNCDT 6500 (with integral pre-amplifier for cable lengths ≤4m):
- RS6500 Rack
- Demodulator
- Sensor cable
- Sensor

System capaNCDT 6510 (with external pre-amplifier for cable lengths >4m):
- RS6500 Rack
- Demodulator
- Sensor cable
- Sensor
- Pre-amplifier
- Pre-amplifier cable

Pre-amplifier CPM6011

- **One of the fastest capacitive controllers in the world, ideal for the measurement of high dynamic processes**
- **Bandwidth 50kHz**
- **High functionality due to integrated DSP**
- **High zero point stability & accuracy**
- **Unmatched temperature stability**
- **Simple measuring range change (50 / 100 / 200 %) using DIP switch**
- **Selectable cable length (0.5 / 1 / 2m) without recalibration**

System structure

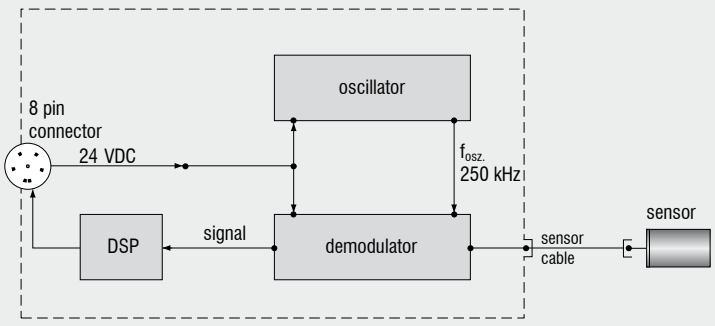
capaNCDT 6350 is a single-channel measurement system with modular designed signal conditioning electronics installed in an aluminium housing. The sensor operates using a high power DSP (Digital Signal Processor) and achieves up to 50kHz (-3dB) bandwidth at the analogue output. The capaNCDT 6350 series is used for demanding measurement tasks and can be used with nearly all capaNCDT sensors.
The system can be adjusted to suit particular target geometries using special tuning.

A measuring system consists of:
- capacitive displacement sensor
- sensor cable
- signal conditioning electronics

Accessories:
- power supply cable and signal output cable
- power supply
- synchronisation cable

Block diagram

Controller DT 6350
Power supply: 24 VDC
Ouput: 0-10 V



Controller type	DT6350
Resolution static	0.005 % FSO
Resolution dynamic	0.1 % FSO (50kHz)
Bandwidth	50kHz
Bandwidth adjustable	20Hz / 5kHz / 20kHz / 50kHz
Linearity	±0.3 % FSO
Max. sensitivity deviation	±0.2 % FSO
Long term stability	≤0.02 % FSO / month
Synchronous operation	yes
Insulator measurement	no
Temperature stability	±0.01 % FSO / °C
Temperature range (operation)	+10 ... +50°C
Temperature range (storage)	-10 … +75°C
Supply	24VDC (9…30V) / 5.5W
	optional: ±15 VDC
Output	0…10V (max. 10 mA short circuit proof)
	optional: 4…20 mA / 0…20mA
Suitable for sensors	all sensors except CS005 and CS08
Sensor cable standard	0.5m; 1m; 2m
Sensor cable (matched)	with fixed assignement: 3m up to 100 % FSO 4m up to 50 % FSO

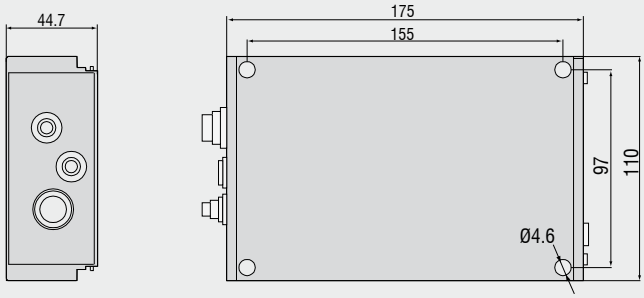
Measuring Range Change

The standard measuring range of the sensor can be adjusted using DIP switches in the controller. If the measuring range is halved for the complete output voltage, the resolution increases. The resolution is reduced correspondingly if the measuring range is doubled.

Controller



- **Nano resolution**
- **High zero point stability & accuracy**
- **Unmatched temperature stability**
- **Any target, also insulator measurement**
- **Measuring system for high requirements**
- **Suitable for all sensors**
- **Robust design**

System structure

capaNCDT 6300/6310 is a single-channel system with modular designed signal conditioning electronics installed in an aluminium housing. Using three-point linearisation, the user can also compensate on site for insulator materials. The pre-amplifier for the 6300 series is integrated in the controller. An external pre-amplifier is used for the 6310 series whereby the cable length can be extended up to 20m, enabling very large distances between sensor and controller. The capaNCDT 6300/6310 series is used for demanding measurement tasks and can be used with all capaNCDT sensors.

A measuring system consists of:
- capacitive displacement sensor
- sensor cable
- signal conditioning electronics

Accessories:
- power supply cable
- power supply
- synchronisation cable
- signal output cable

Special tuning

Special tuning is required for cable lengths above 1m (standard cable length is 1m)

Pre-amplifier CP6001

- **24V (9 – 36V) standard power supply for industrial applications**
- **Suitable for practically all sensors**

System structure

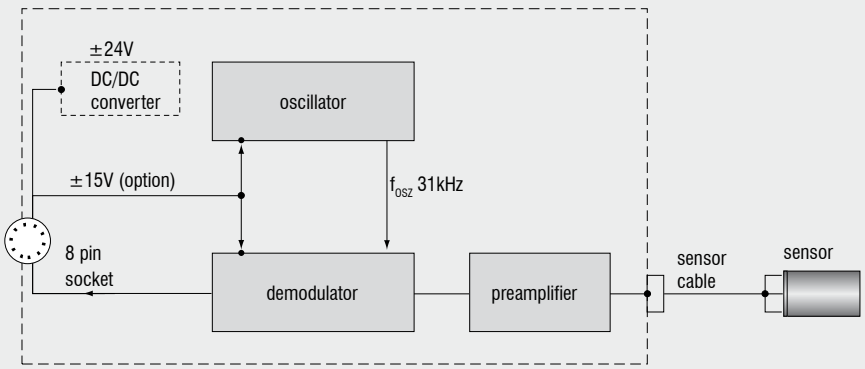
capaNCDT 6100 is a compact single-channel system consisting of the capacitive displacement sensor, the sensor cable and the controller. Using the 2-point linearisation, the user can also carry out compensation on-site which takes account of the individual installation conditions. With the possible power supply between 9 – 36 V, the system can also be operated in passenger cars or trucks. The capaNCDT 6100 provides an outstanding price/performance ratio and is very well suited for common measuring tasks. This system provides high flexibility as it can be operated with practically all capaNCDT sensors.

A measuring system consists of:
- capacitive displacement sensor
- sensor cable
- controller

Accessories:
- power supply cable
- power supply
- synchronisation cable

Block diagram

Power supply: 24 VDC, (9-36 VDC) ±15 VDC
Output: 0-10 V



Controller type	DT6100

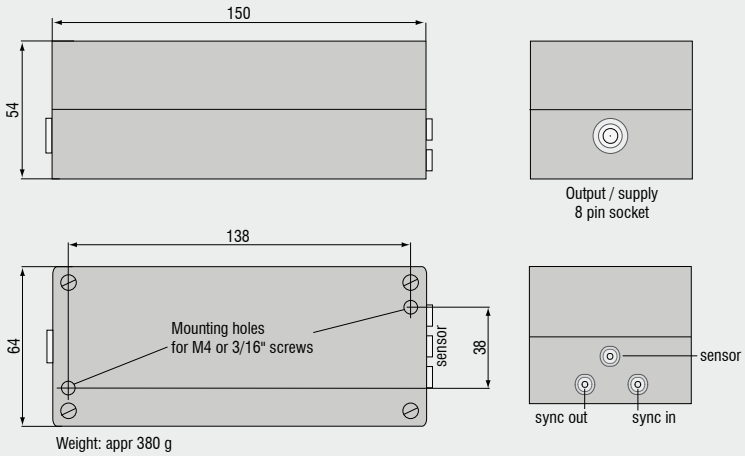
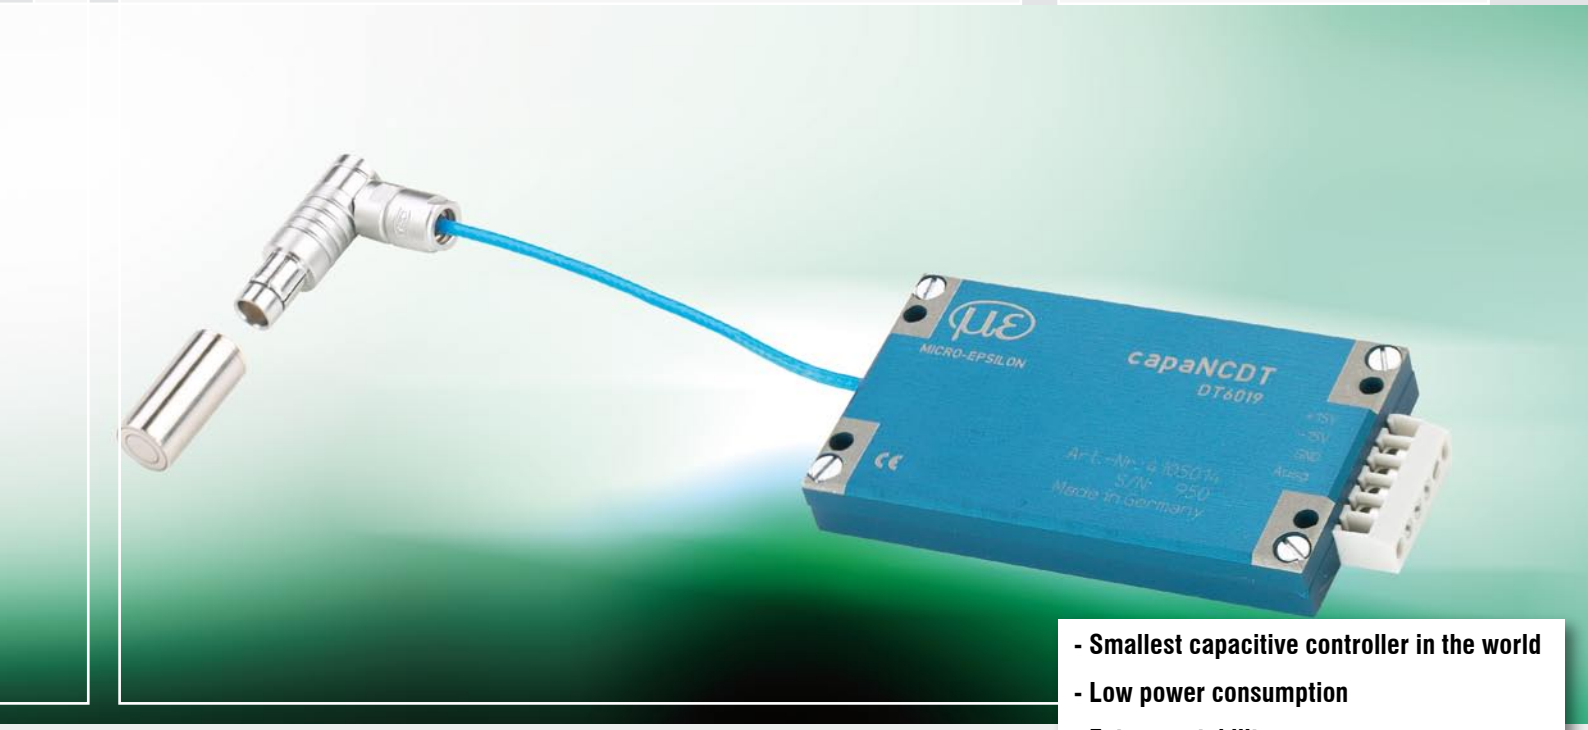
capaNCDT 6100 controller





- **Smallest capacitive controller in the world**
- **Low power consumption**
- **Extreme stability**

System structure

The capaNCDT capacitive measuring system is a single-channel system that uses SMD technology with integrated sensor connection cable and is specially developed for integration with machines and systems. The extremely compact design and economical price are intended for OEM applications. All electrically conducting materials can be used as targets. The capacitive measuring principle ensures high stability, high accuracy and precise measurements. Typical applications are found in positioning, wear measurements, gap measurements, displacement, roundness and others.

The compact design of the controller enables space-saving installations in restricted spaces. Furthermore, the measuring system requires an extremely low supply current.

For this reason, the system also runs by a battery.

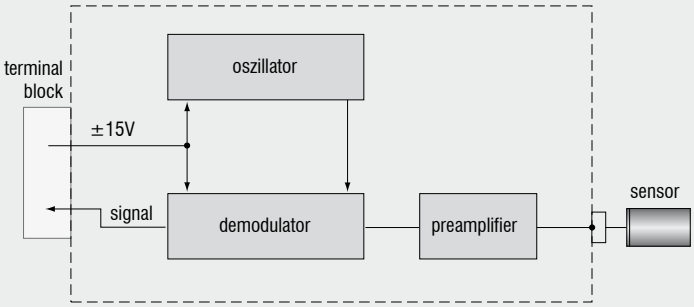
A measuring system consists of:

- Controller DT6019 with integrated cable
- Sensor with female connector
  (except CS005)

Block diagram

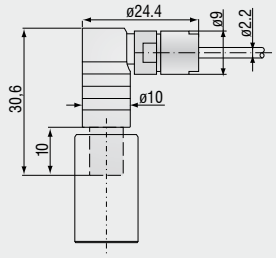
Power supply: ±12 VDC ... ±18VDC

Output: 0-10 V

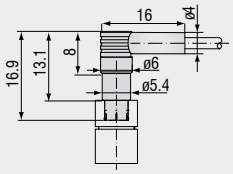


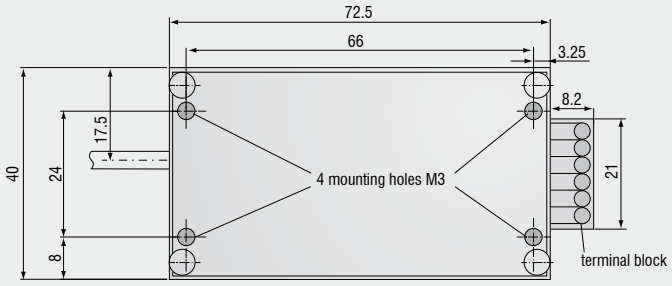
Controller type	DT6019
Resolution static	0.015 % FSO
Resolution dynamic	0.1 % FSO (500Hz)
Bandwidth	0.5kHz
Linearity	±1 % FSO
Max. sensitivity deviation	±0.5 % FSO
Long term stability	≤0.05% FSO / month
Synchronous operation	no
Insulator measurement	no
Temperature stability	±0.05% FSO / °C
Temperature range (operation)	+10°C ... +50°C
Temperature range (storage)	-10°C ... +75°C
Supply	±12…±18 VDC
Power consumption	-7 / +8mA
Output	0 ... 10V (within measuring range), short circuit proof
Weight	60g
Suitable for sensors	all sensors with plug connector, except CS005

DT6019-B with 90° connector for sensors CS1 - CS10

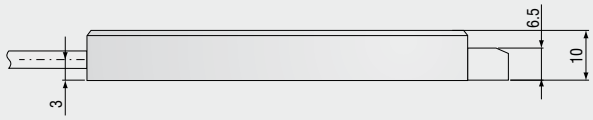


DT6019-C with 90° connector for sensors CS02, CS05, CS08





DT6019 single channel controller

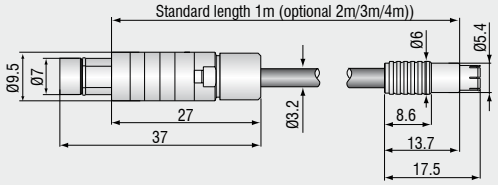


Sensor cable

Sensor and pre-amplifier electronics are connected using a special, double-shielded sensor cable. Cable lengths of 2m, 3m or 4m are optionally available but require special tuning of the pre-amplifier.

	Connector type C: cable for sensors CS005 / CS02 / CS05 / CS08	
cable length	2x straight connectors	1x straight / 1x 90° connector
standard 1m	CC1C	CC1C/90
2m	CC2C	CC2C/90
3m	CC3C	CC3C/90
4m	CC4C	CC4C/90

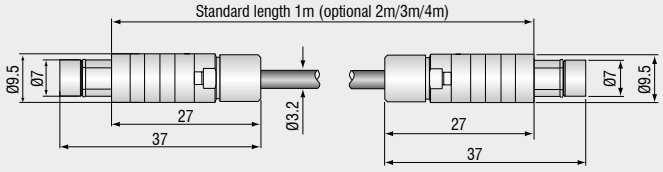
Sensor cable CCxC



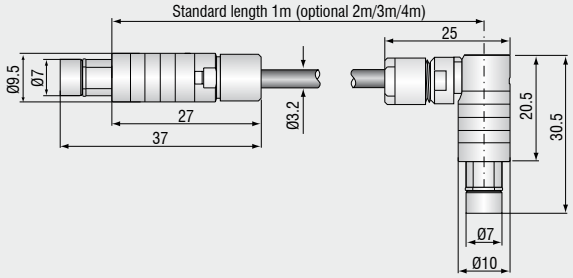
Sensor cable CCxC/90

	Connector type B: cable for sensors CS1 / CS1HP / CS2 / CS3 / CS5 / CS10	
cable length	2x straight connectors	1x straight / 1x 90° connector
standard 1m	CC1B	CC1B/90
2m	CC2B	CC2B/90
3m	CC3B	CC3B/90
4m	CC4B	CC4B/90

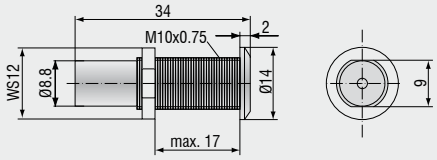
Sensor cable CCxB



Sensor cable CCxB/90



Vacuum feed through WSH



Max. leak rate 1x10e^{-7} mbar · l s^{-1}
Compatible with connector type B

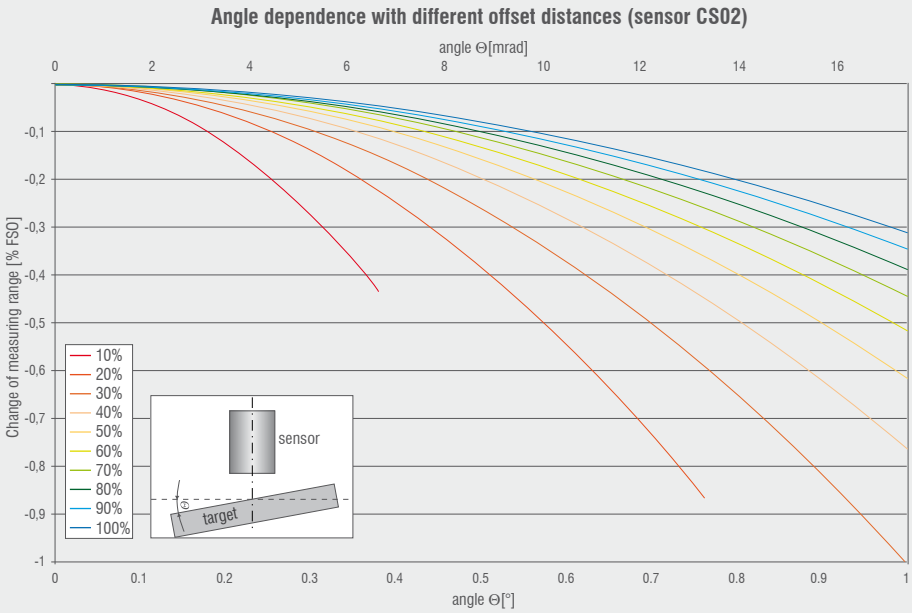
Influence of tilting the capacitive sensor

In the case of tilting of the capacitive sensor, a measurement error must be assumed as the geometric conditions of the field for the target change. In fact, the average distance of the sensor remains constant; however, the edge areas move closer or further away from the target. This results in field distortions, which affect the capacity C according to the following model:

$$C_d(\Theta)=C_d(0)*[1+(\frac{1}{4})*(\frac{R^2}{d^2})*\tan^2\Theta]$$

$$\Delta_x=100*(\frac{d}{d_{MAX}})*\{\frac{1}{[1+(\frac{R^2}{4d^2})*\tan^2\Theta]}-1\}$$

C	*capacity*
Θ	*tilt angle*
R	*measurment area radius*
d	*working distance sensor-target*
d_{MAX}	*sensor measuring range*
Δx	*signal change*



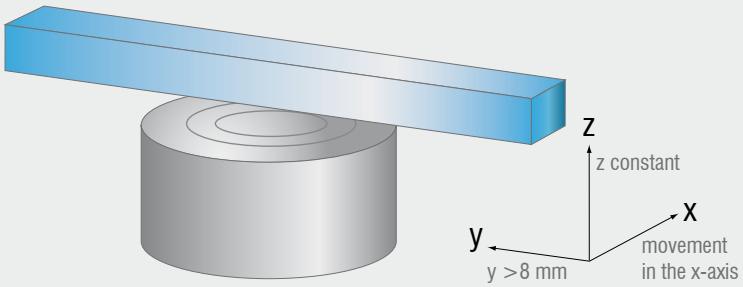
Example illustration of the influence using the CS02 sensor as an example, consideration of a tilt angle of max. 1° for different sensor distances.

In the case of 10% distance in the sensor axis, there is already contact between sensor housing and target at 0.38°; in the case of 20% distance, the contact is at 0.76°. The simulation can be performed for all sensors and installation conditions; tilt angles around a decentralised tilt point can also be calculated.

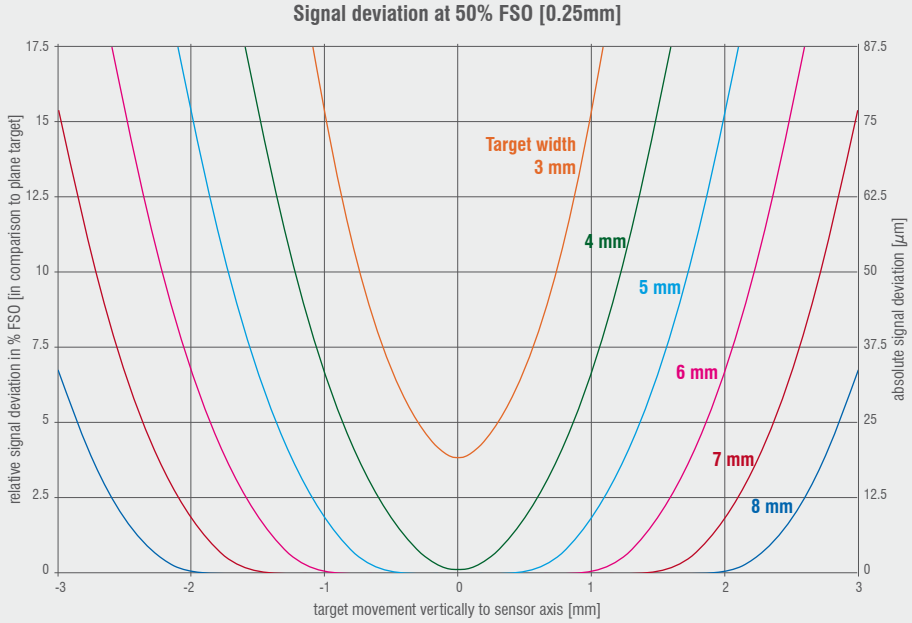
Measurement on narrow targets

The influence of the target width on the measurement signal is shown using the example of a CS05 sensor.

A target extended in the y-axis, narrowed in the x-axis has been varied in different parameters:
- target-sensor distance (z-axis): 0.25mm (measuring range centre)
- width of the target in the x-axis: 3 ... 8mm (21 values)
- displacement of the target in the x-axis (vertical to the sensor axis): 0 ... 3mm (13 values)



In each case, the capacity between electrode and target and its reciprocal (this is proportional to the sensor signal of the controller) were calculated. The diagram shows the deviations from the capacity values for a flat target (large opposite sensor in x and y axes) depending on the target width and displacement.
The smaller the distance between sensor and target, the narrower the target can be. In the example, a centrally placed target with a width of 5mm is sufficient to achieve a stable signal in the centre of the measuring range. This proves that the field does not spread beyond the sensor diameter.



Force effects on the target

Alternating forces between the two electrodes are produced by the electrical field:

$$F = \frac{C * U^2}{(2 * d)} = constant$$

$$F = \frac{\epsilon_0 * \epsilon_R * A * E^2}{2} = constant$$

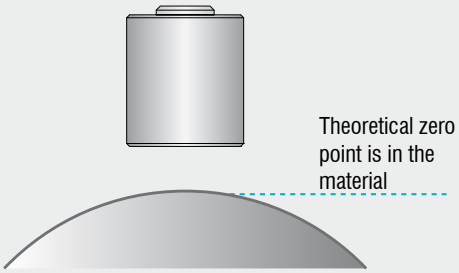
$$F = \frac{1}{2} * E * Q = constant$$

Using the example of a CS1 sensor, which is operated using the DT6300/DT6500 system, a force of approx. 0.23μN is produced. The force however is dependent on the selection of sensor and electronics, not on the sensor's position over the measuring range. The DT6019/6100 systems operate using lower measuring currents, whereby the electrical field and the electrical voltage are lower so that the force is only 0.01μN and so measurement without feedback is assumed.

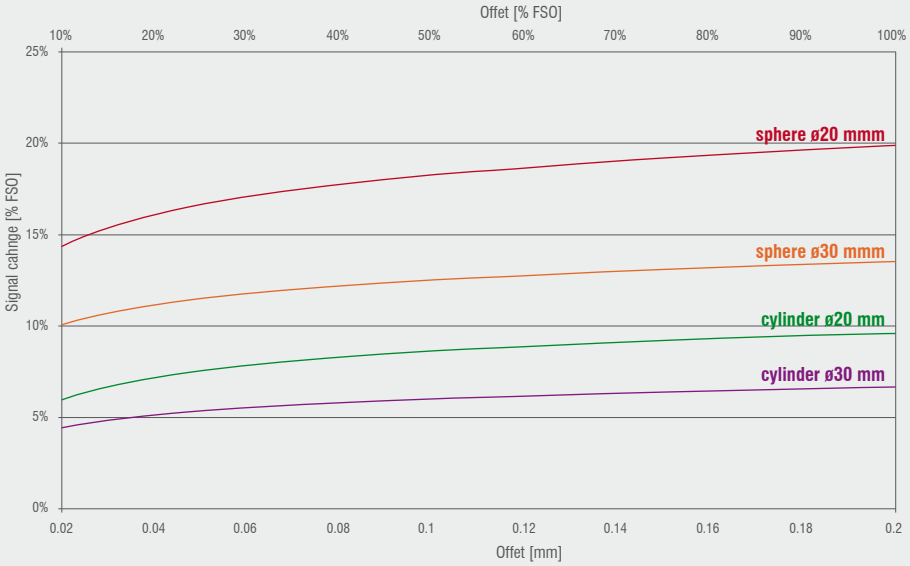
Measurements on spheres and shafts

In practice, it is often necessary to measure curved surfaces. A classic example is shaft runout measurements, where a cylindrical target is measured. Compared to a flat target, there are either more or less significant measured value deviations depending on the bending radius in doing so. This is caused by various effects, e.g. concentration of the field lines at the highest point or a capacity increase due to a larger measuring spot.

In reality, it can be assumed that the bending radius results in a virtual zero point, i.e., the sensor value 0 can no longer be achieved. Due to the integrating function of the capacitive senor over the measurement surface, the virtual, average measuring plane lies behind the surface line. For example, this means that with a 200μm sensor and a roller with an external diameter of 30mm and a gap clearance of 20μm, almost 5% more is indicated, i.e. approx 30μm. As this effect can be calculated, corresponding characteristics can be calibrated in the evaluation electronics.



Signal change: various target geometries (sensor CS02)



Consideration of the conductivity requirements

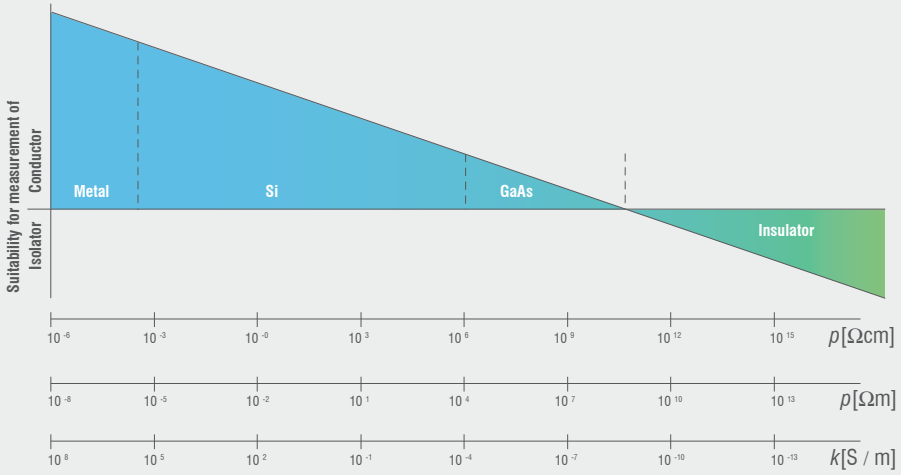
In order to achieve a linear output signal across the complete measuring range, certain requirements for the target or the counter electrode must be complied with.

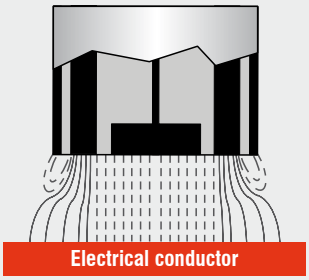
The impedance in the ideal plate capacitor can be shown in the equivalent circuit diagram by a capacitor and a resistor connected in parallel. For measurement against metals, the Ohm part can be disregarded; the impedance is only determined by the capacitive part.

Conversely, only the Ohm part is considered for measurements against insulators. In between, there is the large range of semiconductors. Most semiconductors can be measured very well as electrical conductors. The requirement is that the capacitive part of the total impedance is still significantly larger (>10x) than the ohmic part. This is almost always the case for silicon wafers irrespective of the endowment.

Nevertheless, semiconductors with poor conductivity (e.g. GaAs) can also be measured as conductors under certain circumstances. However, various adjustments are required for this, e.g. reduction of the operating frequency or a temporary, partial increase of the conductivity.

Relation between conductivity and suitability of materials





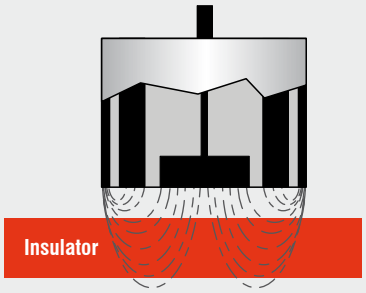
Electrical conductor as target

The capaNCDT system measures the reactance Xc of the capacitor, which changes proportionally with distance. The high linearity of the signal is achieved without further electronic circuitry. This particularly applies to measurements against electrically conductive materials (metals). Changes of the conductivity have no influence on linearity or sensitivity. All conductive or semi-conductive targets are measured without any loss in measurement performance.

No penetration of the fields for electric conductors

As the measurement principle operates without penetration of the fields in the target, even the thinnest targets, e.g. 10µm electrically conductive paint, can be measured.

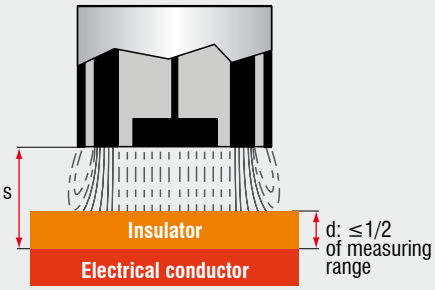
The capacitive measuring process operates with currents in the µA range. This means even the smallest electrical charges are sufficient to make measurements possible. Even very thin metallic objects can guarantee the charge carrier displacement. A target thickness of a few micrometres is sufficient here. The electrical field develops between sensor electrode and target surface; the distance determines the reactance.



Insulators as target

Some capaNCDT systems can also measure insulating materials. In this case resolution and accuracy are reduced.

The field lines penetrate the insulator and join with the electrical sensor housing. The reactance Xc depends on the distance between sensor and insulator. Therefore a constant thickness and permittivity of the insulator is necessary. Factory calibration/compensation is strongly recommended.



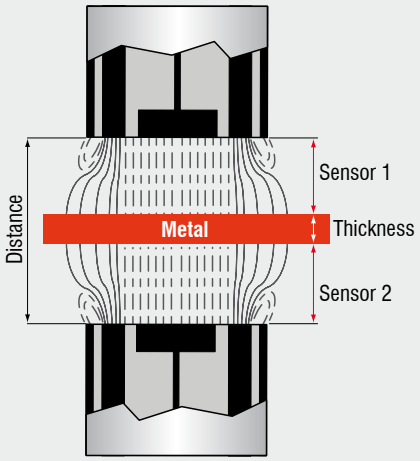
Thickness measurement of insulators

The capaNCDT system can also be used for the linear thickness measurement of insulators. The field lines penetrate the insulator and join with the electrical conductor. If the thickness of the insulator changes, this influences the reactance Xc of the sensor. The distance to the electrical conductor must therefore be constant.

$$\frac{C}{C_0} = \frac{1}{(1-(\frac{d}{s})*(1-\frac{\epsilon_1}{\epsilon_2}))}$$

$$\epsilon_1 = \epsilon_0 * \epsilon_{r1}, \epsilon_2 = \epsilon_0 * \epsilon_r$$

d Target thickness
s Measuring gap
ε_1 Permittivity air
ε_2 Permittivity insulator



Thickness = Distance - (Sensor 1 + Sensor 2)

Thickness measurement of metals

Two-sided thickness measurement of metals is made possible by installing the sensors opposite each other. Strip thicknesses in the µm range can be measured using this method. Each sensor generates a linear output signal dependent on the distance between sensor surface and target surface. If the sensor distance is known, the thickness of the target can be determined easily.

Due to the capacitive principle, the measurement is only performed against the surface without penetrating the target. If the measuring points are synchronised, measurement against non-grounded targets is possible.

Specific sensors for OEM applications

Application examples occur again and again where the standard versions of the sensors and the controller are performing at their limits. For these special tasks, we modify the measuring systems exclusively according to your individual requirements. Changes often requested include for example modified designs, target coordination, mounting options, individual cable lengths, modified measuring ranges or sensors with integrated controller.

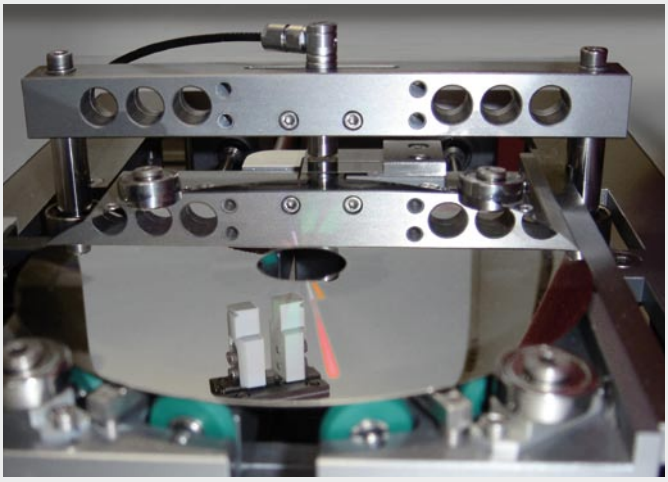
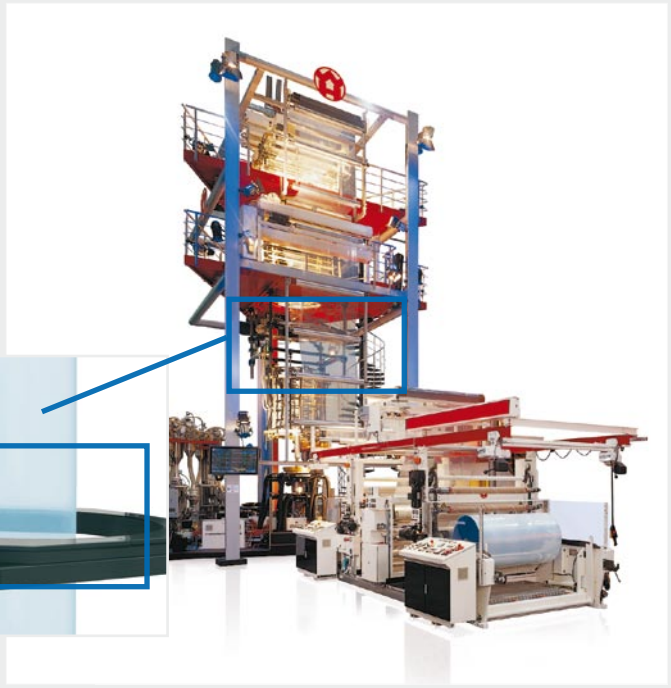
Thickness measurement of dies for optical data carriers

Previously, the data was transferred to a master system using a laser to reproduce CDs, DVDs, HD-DVDs or Blu-ray discs by pressing. A thin layer of nickel is applied using galvanisation to the silicon or glass carrier (substrate). The absolute thickness values of the nickel layer are required in order for the exact control of the galvanisation bath. Capacitive sensors from Micro-Epsilon are used to measure the thickness and profile. A sensor is positioned above and below the die, which is then moved between the sensors during measurements. Using the two units for distance information, the thickness is determined very precisely using the differential method.



Modular measuring system for the profile measurement of blown films

The measuring of the film profile already on the film bubble provides important data for extrusion control. In order to make the process as efficient as possible, a modular blown film measuring system was designed by Micro-Epsilon, which is installed immediately after the calibration cage. The system is available with contact and non-contact sensors. The sensor system used for profile measurement is based on the capacitive measuring principle, which reliably and accurately ascertains the profile of the film. The capacitive sensors used can be distinguished by their extreme precision and signal quality.



Contacting sensor

Non-contact sensor

Measurements on wafers and semiconductors

Extreme accuracies are required in the semiconductor industry in order to design processes and products efficiently. Capacitive sensors from Micro-Epsilon are used, among other things, for the positioning, displacement measurement and thickness measurement in the semiconductors area.

Capacitive displacement sensors are used for adjustment with nanometre precision of lenses in optical systems for wafer exposure.
